

Ta → Al $S/B_{\text{particle}} = 0.335$ (est.) / 0.183 (incl. bounds)

Al → Hf $S/B_{\text{particle}} = 0.332$ (est.) / 0.182 (incl. bounds)

Per-channel factors are NUCLEUS's own published values (>99.8% muon-induced, Pb ÷50, B₄C×COV ÷25), ASSUMED achievable by a future shield/veto — NOT rigorous credit:

they are CaWO₄ event-rate reductions and most need the COV/MV veto the wafer does not geometrically fit (Phase 8).

spectrum: linear $E_{\text{rec}} = 0.497 E_{\text{dep}}$, NO saturation and NO trigger. The solid-to-dotted gap is the trigger rolloff below ~1 eV and saturation above the onset. Dotted curves are spikier because R smooths the deposit spectra's MC noise -- that is samp
