

Ta → Al $S/B_{\text{particle}} = 0.759$ (est.) / 0.516 (incl. bounds)

Al → Hf $S/B_{\text{particle}} = 0.743$ (est.) / 0.509 (incl. bounds)

The 100× suppression is an ASSUMED placeholder — not derived, and deliberately NOT transferred from NUCLEUS, whose ~5 and ~50 are event-rate reductions in CaWO₄ that embed a target response which is not Ge's.

the SAME deposits with NO bandwidth saturation (linear $E_{\text{rec}} = 0.497 E_{\text{dep}}$, trigger applied); solid minus dotted IS the saturation cost. Dotted curves are spikier because R smooths the deposit spectra's MC noise -- that is sampling scatter, not σ
